## Lesson 10: Worksheet 10.1 – Vampire robot

In this challenge-based activity, you will apply everything you have learned so far to create a program with lots of interesting behaviours for your Edison robot to perform while transformed into a vampire robot.

To turn your Edison into a vampire robot, we will use object-oriented code.

### Objects and classes in Python

Python is an object-oriented programming language. Object-oriented code is a powerful way of reducing complexity inside a program. That's why many programmers use object-oriented code in large, complicated programs.

In an object-oriented programming language, rather than just using standalone variables and functions, programs can also use 'objects'.

An object is a collection of functions and variables which are related to each other. Objects are defined by a 'class'.

A class (also called a class definition) is like a blueprint that describes how to make an object.

In a program, you can create lots of different objects from a class and then manipulate these objects individually in your program for different purposes. All of the objects created from the class will have the same 'blueprint' when they are created, but you can then do different things to different objects throughout your program.

### Example: class 'Shape'

The most common example of a class is a Shape.

All shapes, like squares, triangles and hexagons, have common attributes. For example, all shapes have some number of sides and some number of vertices. There are also common things you do with shapes, like find the area or the perimeter of the shape.

We can use these common elements to create a class for Shape in Python. By creating the class, we are setting up a blueprint with just the known, common elements. We will then be able to create many different objects from that class, such as 'square' and 'triangle'.

The syntax for defining a class in Python is 'class' and then the name you want to give that class, followed by a colon (:). For example:

```
class Shape:
```

Anything you include as indented code in the lines following this is inside the class definition.

Look at the following example of a class for Shape in Python:

```
class Shape:
    def __init__(self,x,y):
        self.x = x
        self.y = y

    def area(self):
        return self.x * self.y

    def perimeter(self):
        return 2 * self.x + 2 * self.y
```

This class says that the blueprint for any object created from class Shape will have two input parameters (x and y). The class also defines three functions: 'init', 'area' and 'perimeter'.

### The `__init__` function and 'self'

Each class must always have an `__init__` function.

The `__init__` function is start-up code. The term 'init' stands for 'initialisation'.

When the program needs to create an object, the program goes into the class definition and runs the `__init__` function. This function contains code which sets up the object, which typically means setting the start values of the object variables.

Functions in a class must always have 'self' as their first parameter. This tells the created object to use its own functions and variables.

### Example: object 'rectangle'

Once we have created a class definition, we can use it to create objects in our program.

Let's say we want to create an object 'rectangle' in class Shape.

In Python, when you want to create an object from a class, you use the syntax `object_name = class_name(parameters)`.

Look at the example of creating object 'rectangle':

```
rectangle = Shape(100,45)
```

In a program, this calls the `__init__` function, which runs, creating an object 'rectangle' using the blueprint from the Shape class definition. The object 'rectangle' is set to have 100 be the 'x' input value and 45 as its 'y' input value. (You don't need to put in 'self' – that's only a reference for the program to know where to look.)

Once the program creates the object, it can access that object's functions as defined by the class.

Name\_\_\_\_\_

To call one of these functions in Python, you use the syntax  
object\_name.function\_name(parameters).

For example:

```
rectangle.area()
```

In this example, the rectangle.area() function will return the value of the rectangle object's 'x' input parameter multiplied by its 'y' input parameter.

One way to use this particular function would be to store this value in a variable in your program. For example:

```
AreaOfRectangle = rectangle.area()
```

### Setting up a class in EdPy

In EdPy, we can use a class to create different objects in a program for Edison.

Here is a simple class for a Vampire robot with an \_\_init\_\_ function and two other functions: one for daytime behaviour for the robot and one for night time behaviour. The Vampire class also contains a variable for the age of the robot:

```
class Vampire:

    def __init__(self,age):
        self.age = age

    def doDayTimeBehaviour(self):
        Ed.LeftLed(Ed.OFF)
        Ed.RightLed(Ed.OFF)
        Ed.PlayTone(Ed.NOTE_A_7, self.age)
        while Ed.ReadMusicEnd() == Ed.MUSIC_NOT_FINISHED:
            pass
        Ed.TimeWait(1, Ed.TIME_SECONDS) # for debugging purposes and as a placeholder

    def doNightTimeBehaviour(self):
        Ed.RightLed(Ed.ON)
        Ed.LeftLed(Ed.ON) # for debugging purposes and as a placeholder
```

This class definition will allow you to create different Vampire objects.

You can then use these Vampire object in a program for your Edison robot.

Name\_\_\_\_\_

Write the following code and check that you understand what is happening in the program:

```
1
2 #-----Setup-----
3
4 import Ed
5
6 Ed.EdisonVersion = Ed.V2
7
8 Ed.DistanceUnits = Ed.CM
9 Ed.Tempo = Ed.TEMPO_MEDIUM
10
11 #-----Your code below-----
12
13 myEdisonVampire = Vampire(21)
14
15 while True:
16     # if it is the daytime
17     if Ed.ReadLeftLightLevel() > 100:
18         myEdisonVampire.doDayTimeBehaviour()
19     #it is night time
20     else:
21         myEdisonVampire.doNightTimeBehaviour()
22
23 class Vampire:
24
25     def __init__(self,age):
26         self.age = age
27
28     def doDayTimeBehaviour(self):
29         Ed.LeftLed(Ed.OFF)
30         Ed.RightLed(Ed.OFF)
31         Ed.PlayTone(Ed.NOTE_A_7, self.age)
32         while Ed.ReadMusicEnd() == Ed.MUSIC_NOT_FINISHED:
33             pass
34         Ed.TimeWait(1, Ed.TIME_SECONDS) # for debugging purposes and as a placeholder
35
36     def doNightTimeBehaviour(self):
37         Ed.RightLed(Ed.ON)
38         Ed.LeftLed(Ed.ON) # for debugging purposes and as a placeholder
39
```

## Your turn:

### Task 1: Design the Vampire behaviours

Now it is time to design some more interesting behaviours for your Vampire robot. Be creative! You can make your robot react to button pushes, claps and obstacles. Consider using event handling in your program. You can make multiple vampire objects with whatever ages you want. You can also modify the base program so that your objects have multiple input parameters.

Think about what you want to include in your program, then work through your program design by first creating flowcharts and then pseudocode based off of the flowcharts.
